Persistent data structures

Partially
Persistent
Search Trees

OOOO
Specification

Verifying Find

Verifying Insert

Discussion

A data structure is said to generate a new version when it is modified. A **persistent data structure** allows users to have access to previous versions and act on them. In contrast, we cannot retrieve previous versions in **ephemeral data structures**.

We can perform lookup operations on **partially persistent** data structures, while **fully persistent** data structures allow us to **modify** on them (and hence the history of versions will not be linear any more).

Persistent search trees

Partially Persistent Search Trees 00000

Specification

Verifying Find

Verifying Insert

Discussion

We focus on tree structures for now. There are three ways to implement a persistent search tree.

- ► Path copying
- ► Fat node method
- ► Node copying (constant amortized time/space complexity for lookup and modification, not covered)

Path copying

Verifying Insert

0000

Discussion

We introduce a *ghost variable* ValueSets that allows us to infer all the values the tree contains for each version.

E.g., 3 in ValueSets[5] if and only if value 3 exists in the fifth version of the tree.

Partially Persistent Search Trees

Specification

•00000

Verifying Find

Verifying
Insert

Discussion

High-level specification

We introduce a *ghost variable* ValueSets that allows us to infer all the values the tree contains for each version.

E.g., 3 in ValueSets[5] if and only if value 3 exists in the fifth version of the tree.

However, since ValueSets is a field variable, we don't want to update this field for all the nodes every time the data structure gets updated.

In our current implementation, we have ValueSets that is a sequence of the actual value sets, and an associated ValueSetsVersions of the same length that tells us the version of each entry in ValueSets. ValueSetsVersions is a subsequence of [n], where n is the latest version we are at.

High-level specification

Partially Persistent Search Trees

Specification

000000 Verifying Find

Verifying Insert

Discussion

Suppose ValueSets only gets updated at versions [1, 3, 5]. To guery the value at version 2, we perform binary search on the list of versions and return the version that is closest to but smaller than our guery version. We call the returned version **maxmin** version.

High-level specification

Partially Persistent Search Trees Specification

000000 Verifying Find

Verifying Insert

Discussion

Suppose ValueSets only gets updated at versions [1, 3, 5]. To guery the value at version 2, we perform binary search on the list of versions and return the version that is closest to but smaller than our query version. We call the returned version maxmin version.

Here, 3 is the maxmin version if our guery version is 4. Of course, if the query version is present in the version sequence, the maxmin version is equal to the query version.

(Partial) specification for Find, Insert, and Remove

Partially
Persistent
Search Trees
OOOO
Specification
OOOOO

Verifying Find

Verifying Insert

Discussion

By writing a helper function ValueSetAt(version:int):(res:set<int>) that returns the correct value set for all possible query versions., we can loosely specify the key postconditions of our interface as follows.

```
function Find(version:int, value:int): (res: bool)
...
ensures res <==> value in ValueSetAt(version)

method Insert(version:int, value:int): (res: Node?)
...
ensures value in ValueSetAt(version)

method Remove(version:int, value:int): (res: Node)
...
ensures value !in ValueSetAt(version)
```

Initial attempt to specify the invariant for ValueSets

Partially Persistent Search Trees

Specification

Verifying Find

Verifying Insert

Discussion

We initially tried to mimic the specification style of BinarySearch.dfy in the Dafny repo.

```
ghost predicate Valid()
 reads this, Repr
 ensures Valid() ==> this in Repr
  (left == null && right == null ==>
   Contents == {data}) &&
  (left != null && right == null ==>
   Contents == left.Contents + {data}) &&
  (left == null && right != null ==>
   Contents == {data} + right.Contents) &&
  (left != null && right != null ==>
   left.Repr !! right.Repr &&
   Contents == left.Contents + {data} + right.Contents)
}
```

Partially Persistent Search Trees

Initial attempt to specify the invariant for ValueSets

For example, when lefts is empty but rights is not, the invariant is expressed as

Partially Persistent Search Trees OOOO Specification OOOOOO Verifying Find

Verifying Insert

Discussion

Initial attempt to specify the invariant for ValueSets

```
|rights| > 0 && |lefts| == 0 ==>
  (forall i | 0 <= i < |ValueSets| ::
   exists j, k \mid 0 <= j <= i < \mid values\mid
                  && 0 <= k <= i < |rights| ::
    MaxMin(ValueSetsVersions[i], j, valuesVersions)
    && MaxMin(ValueSetsVersions[i], k, rightsVersions)
    && (rightsVersions[k] == ValueSetsVersions[i]
        || valuesVersions[j] == ValueSetsVersions[i])
    && (rights[k] != null ==>
          (exists x | 0 <= x < |rights[k].ValueSets| ::</pre>
            MaxMin(ValueSetsVersions[i], x, rights[k].ValueSetsVersions)
            && ValueSets[i] == {values[j]} + rights[k].ValueSets[x]))
    && (rights[k] == null ==> ValueSets[i] == {values[j]}))
```

Considering all possible cases for the invariant to specify ValueSets leads to 50 lines of formulas, where most of them contain three quantifiers. \implies Timeout! (set to be 5 minutes for this project)

Using helper functions to specify

Partially Persistent Search Trees

Specification 00000

Verifying Find

Verifying Insert

Discussion

The convoluted specification is mostly due to 1) the "gap" in the version sequences and 2) different cases we need to consider to preserve the well-formedness of formulas.

Using helper functions to specify

Partially Persistent Search Trees Specification 00000 Verifying Find

Verifying Insert

Discussion

The convoluted specification is mostly due to 1) the "gap" in the version sequences and 2) different cases we need to consider to preserve the well-formedness of formulas.

We can instead use helper functions to hide this complexity in our specification.

```
forall v | valuesVersions[0] <= v ::</pre>
  ValueSetAt(v) == { ValueAt(v) } + LeftValueSetAt(v) + RightValueSetAt(v)
```

Using helper functions to specify

Partially Persistent Search Trees Specification 00000

Verifying Find

Verifying Insert

Discussion

The convoluted specification is mostly due to 1) the "gap" in the version sequences and 2) different cases we need to consider to preserve the well-formedness of formulas.

We can instead use helper functions to hide this complexity in our specification.

```
forall v | valuesVersions[0] <= v ::</pre>
  ValueSetAt(v) == { ValueAt(v) } + LeftValueSetAt(v) + RightValueSetAt(v)
```

Note: we need to rewrite the preconditions of these helper functions in order to avoid infinite loops.

Verifying Find

Partially Persistent Search Trees

Specification

Verifying Find

•000000

Verifying Insert

Discussion

The interface of Find is simple and it can be verified under 500ms.

```
function Find(version: int, value: int) : (res: bool)
 reads Repr
  requires BasicProp() && ValueSetProp() && BinarySearchProp()
  ensures res <==> value in ValueSetAt(version)
  if (version < valuesVersions[0]) then
    false
  else
    if version < valuesVersions[0] then
      assert value !in ValueSetAt(version):
      false
    else
      assert isBST(version):
      . . .
```

Verifying Find

Partially Persistent Search Trees

Specification

Verifying Find •000000

Verifying Insert

Discussion

The interface of Find is simple and it can be verified under 500ms.

```
function Find(version: int, value: int) : (res: bool)
 reads Repr
  requires BasicProp() && ValueSetProp() && BinarySearchProp()
  ensures res <==> value in ValueSetAt(version)
  if (version < valuesVersions[0]) then
    false
  else
    if version < valuesVersions[0] then
      assert value !in ValueSetAt(version):
      false
    else
      assert isBST(version):
      . . .
}
```

Omitting the line assert isBST(version) makes the solver return unknown under 1s.

Quantifier instantiation and E-matching

Partially Persistent Search Trees

Specification

Verifying Find ○●○○○○○

Verifying Insert

Discuss

Discussion

Z3 handles quantifier instantiation using **E-matching** or **model-based quantifier instantiation** (MBQI). The default setting of Dafny uses E-matching only.

Quantifier instantiation and E-matching

Partially
Persistent
Search Trees
OOOOO
Specification

Insert

OOO

Discussion

Discussion

Z3 handles quantifier instantiation using **E-matching** or **model-based quantifier instantiation** (MBQI). The default setting of Dafny uses E-matching only.

A **trigger** is a set of non-ground terms. Terms in a trigger need to cover all quantified variables in the input formula. E-matching looks for ground terms matching the triggers to determine when to perform quantifier instantiation.

A term is said to be **active** if the current partial model gives it an interpretation.

Partially Persistent Search Trees OOOOO Specification

Discussion

000

Suppose our proof goal is $\forall x.\{f(g(x))\}f(g(x))\neq x$. Additionally, we have g(a)=c, g(b)=c, and $a\neq b$.

Partially
Persistent
Search Trees
OOOOO
Specification

Verifying Find

Verifying Insert

Discussion

Suppose our proof goal is $\forall x.\{f(g(x))\}f(g(x))\neq x.$ Additionally, we have $g(a)=c,\ g(b)=c,$ and $a\neq b.$

Since there is no active ground term of the form f(g(t)), the quantifier is not instantiated. Z3 returns unknown. If a more permissive trigger $\{g(x)\}$ is used, Z3 will return unsat.

Partially Persistent Search Trees

Specification

Verifying Find 0000000

Verifying Insert

Discussion

Suppose our proof goal is $\forall x. \{f(x)\} f(x) = f(g(x)).$

Partially Persistent Search Trees Specification

Verifying Find 0000000 Verifying

Insert

Discussion

Suppose our proof goal is $\forall x. \{f(x)\} f(x) = f(g(x)).$

The quantifier gets instantiated whenever a term of the form f(t)is active, and such an instantiation will bring a fresh ground term f(q(t)), which causes another instantiation...etc. In this case, if we have a more restrictive trigger $\{f(g(x))\}\$, we can avoid the so-called **matching loops**.

Partially Persistent Search Trees OOOO Specification

Verifying Find

Verifying Insert

Discussion

As the examples have shown, in some cases, a more permissive trigger is preferred, while in other cases, a more restrive trigger is needed.

Partially
Persistent
Search Trees
OOOO
Specification

Verifying Find

Insert

Discussion

As the examples have shown, in some cases, a more permissive trigger is preferred, while in other cases, a more restrive trigger is needed.

That does not mean we can always resolve problems stemming from triggers. For example, $\forall x. f(x) = g(f(x)) \land g(x) = f(g(x)).$

Triggers in Dafny

Partially

OOOOOO

Verifying
Insert

OOOO

Discussion

Heuristics for selecting triggers in Z3 is deemed as unstable in a lot of literature. Dafny implements its own trigger selection algorithm in hope of more predictable behaviors, and users can also specify the triggers explicitly at the Dafny level.

Unfortunately, it does not resolve all possible issues from triggers. New skolem constants may be introduced at the SMT solver level and users cannot specify the triggers explicitly at the verifier level.

The key assertion in Find

```
Persistent
Search Trees

0000
Specification

00000
Verifying Find

00000
Verifying
Insert

0000
```

Partially

```
function Find(version: int, value: int) : (res: bool)
 reads Repr
 requires BasicProp() && ValueSetProp() && BinarySearchProp()
 ensures res <==> value in ValueSetAt(version)
 if (version < valuesVersions[0]) then
   false
 else
   if version < valuesVersions[0] then
     assert value !in ValueSetAt(version):
     false
   assert isBST(version):
      . . .
```

The assert isBST(version) in our proof activates the trigger to allow quantifier instantiation.

The simplified Insert

POO

We collected various examples that demonstrate surprising behaviors of the prover/verifier. Unfortunately, we don't know how to explain these behaviors.

For example,

```
assert ValueSetsAtVersion(version).0 >= 0;
assert ValueSetsAtVersion(version).0 >= 0 ==>
  valuesVersions[i] <= ValueSetsAtVersion(version).0;</pre>
```

These two assertions are part of our proof for a function and can be verified under 500 ms. However, Dafny times out when we add

```
assert valuesVersions[i] <= ValueSetsAtVersion(version).0;</pre>
```

right after these two assertions.

Understanding why formal proofs fail

Partially Persistent Search Trees

Specification 00000

Verifying Insert

Discussion 0•0

- ▶ We are dealing with undecidable and/or intractable problems.
- ► There is a lack of rigorous analysis of some important heuristics implemented in Z3 (e.g., triggers selection).
- ► Proof complexity itself is an active research area (what formulas lead to long refutation proofs?).

Theoretical constraints aside, can we write formal proofs more efficiently with better engineering?

Proofs debugging

Partially
Persistent
Search Trees
OOOOO

oooooo Verifying Find

oooooo Verifying

Insert

Discussion

No widely agreed-upon definition of "bugs" in SMT solvers, but in the VCC project, they have

- Model viewers for debugging the models
- Axiom profilers for tracing profiles
- Z3 inspector for sampling profiles

Unfortunately, all these tools are no longer maintained, but insights into why we keep getting timeouts are difficult to attain without effective debugging tools.

Q&A and Discussion

- ► Is there a better way to write the specification for this data structure?
- ► To what extend can we make formal proofs more or less like pen-and-paper proofs?
- ► Why is heap reasoning difficult?
- ▶ Is there a better way to debug formal proofs?
